BP1 | Rice sourcing regions

A practical guide to the compact Streamlit dashboard and its four views

Business question. Which Vietnamese regions have meaningful rice production, and how do scale, growth, and historical variability affect sourcing assessment? The dashboard describes potential supply. Supplier availability, price, quality, and logistics still require separate checks.

How to use the dashboard

The unlabeled year menu covers 2015-2024 and changes charts 1, 2, and 3. The region menu changes only chart 2. Chart 3 uses up to ten years of history ending in the selected year; chart 4 always shows 2010-2024. Hover over marks for exact values. Select Data and methods for the current provincial profile and the 2024 regional benchmark.

2024 benchmark

Provincial records sum to **43.45 million tonnes** in 2024. The Mekong Delta contributes **24.52 million tonnes (56.4%)**, making it the dominant production region in this historical mapping. The table provides the full regional context.

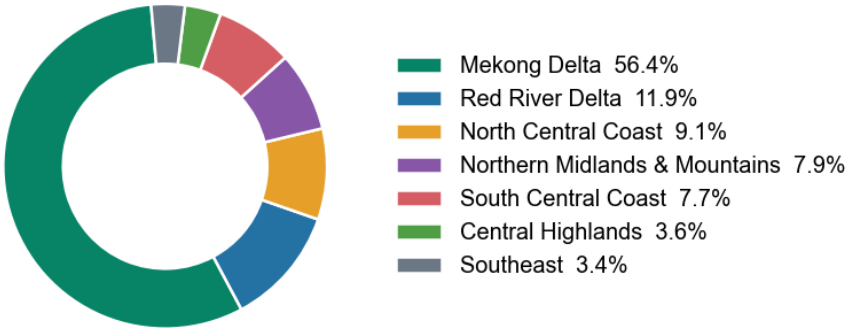

Region	Production (million t)	National share	2015-24 CAGR	Growth volatility
Mekong Delta	24.52	56.4%	-0.47%	3.39 pp
Red River Delta	5.16	11.9%	-2.56%	3.48 pp
North Central Coast	3.94	9.1%	+0.37%	3.81 pp
Northern Midlands & Mountains	3.44	7.9%	-0.33%	2.02 pp
South Central Coast	3.37	7.7%	+1.12%	5.75 pp
Central Highlands	1.57	3.6%	+2.92%	4.03 pp
Southeast	1.46	3.4%	+0.64%	1.24 pp

Growth volatility is the standard deviation of annual year-on-year production growth, expressed in percentage points. A low regional figure can conceal volatile individual provinces.

Read the selected-year views

Both previews below use 2024 and update when the year control changes in Streamlit.

1 | Regional share - pie chart

What it shows. Each slice is a region's share of total provincial rice production in the selected year. The dashboard title above the pie displays the national sum, outside the chart to keep the labels clear. In 2024, the Mekong Delta accounts for 56.4%, followed by the Red River Delta at 11.9%.

Sourcing meaning. The Mekong Delta merits the first supplier scan because of its scale, but the share chart does not show how much is tradable or available to a specific buyer. Smaller regions remain useful alternatives for diversification.

2 | Region-to-province flow - Sankey chart

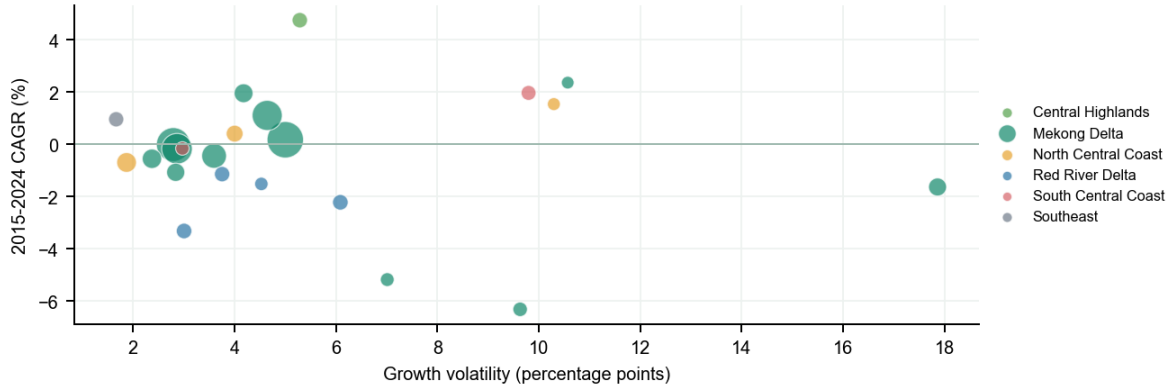

What it shows. The selected region is the single source. The five largest provinces are shown separately; the rest are combined as Other provinces. Flow width represents production, and every destination adds back to the regional total. Pale links and a single-region view keep labels visible.

Sourcing meaning. For the 2024 Mekong Delta, Kiên Giang (4.71 million tonnes) and An Giang (4.07 million tonnes) are major contributors. Other provinces together still account for 7.00 million tonnes, so a plan focused only on the top two would overlook a substantial portion of potential supply.

Read the historical views

The provincial profile follows the selected year; the regional line chart retains the full 2010-2024 history.

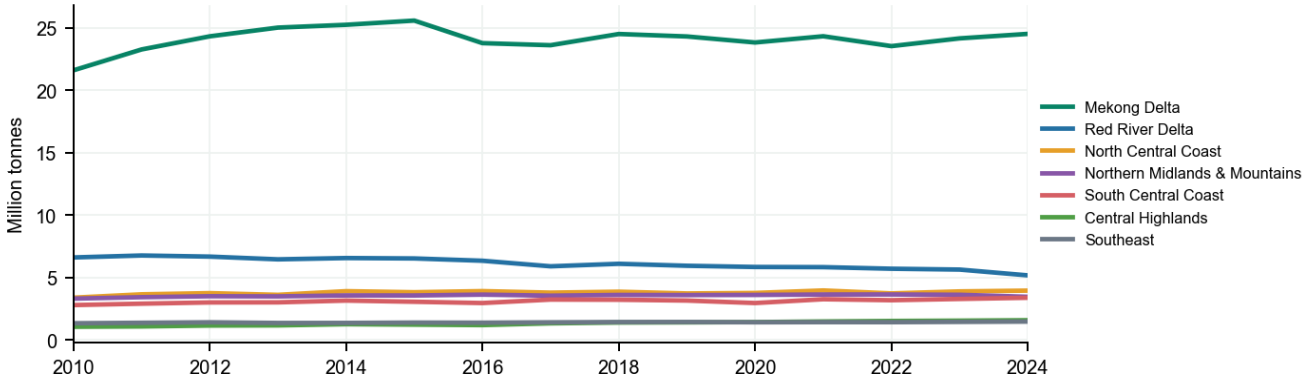

3 | Provincial profile - bubble chart

What it shows. The preview uses 2024. Each bubble is a province producing at least 500 thousand tonnes in the selected year. Size shows that year's output; the vertical axis shows CAGR and the horizontal axis shows the sample standard deviation of annual growth. Both rates use a trailing window from max(2010, year minus 9) through the selected year. Thus 2024 uses 2015-2024, while 2019 uses 2010-2019. Hover for province names and exact values.

Sourcing meaning. Large bubbles with low volatility may warrant closer supplier assessment. High growth does not guarantee stability, and a volatile province can still contribute important volume. The 500-thousand-tonne cutoff is a display filter. It is recalculated for the selected year; the Data and methods table retains all 63 provinces.

4 | Regional production over time - line chart

What it shows. Seven lines compare annual regional production from 2010 through 2024 in absolute units. The Mekong Delta stays far above other regions, rising from 21.60 million tonnes in 2010 to 24.52 million tonnes in 2024; it reached 25.58 million tonnes in 2015. The Red River Delta trends down to 5.16 million tonnes in 2024.

Sourcing meaning. Compare sustained levels and direction across years, not one isolated point. The common vertical scale makes small-region movements appear compressed, so hover for values and use the regional table for growth and volatility rates.

Data, definitions and limits

NSO PX-Web tables V06.13 (area), V06.14 (yield), and V06.15 (production) cover 63 historical provinces for 2010-2024. The team's seven-region JSON assigns provinces to regions. Production is measured in thousand tonnes in the source files; the PDF converts some values to million tonnes. CAGR uses 2015 and 2024 endpoints; volatility uses the nine annual growth rates from 2016-2024. These are descriptive statistics, not forecasts or causal effects. Rounded provincial sums may differ slightly from published national totals. Region and province definitions follow the supplied historical mapping and should not be interpreted as current administrative boundaries.
